SARAS Self and Peer Assessment

Module: CET257 Enterprise Project
Team: Team 9 — SARAS Labs
Members: Rijan Kapur Poudel and Sushank Jung Rawal
Purpose: Evaluate both members against the seven assessment categories and explain the verified contribution allocation recorded in their assessment sheets.

1 Recorded contribution allocation

The two individual Self and Peer Assessment spreadsheets, dated 8 October 2026, record **60% for Rijan Kapur Poudel and 40% for Sushank Jung Rawal**. The allocation has been verified. Both sheets assess the same two members, including the named student's own contribution, and each totals 100%.

Table 1 Recorded contribution allocation

Team member	Contribution	Main responsibilities informing the judgement
Rijan Kapur Poudel	60%	Project coordination, backend and system logic, database, authentication, 3D technical integration, technical documentation and demonstration operation
Sushank Jung Rawal	40%	Frontend development, UI/UX, navigation, responsive layouts, visual identity, branding and presentation visuals
Total	100%	Includes both members' shared interface, branding and promotional website work

The percentages express an overall assessment of contribution. They are not measured hours, separate marks for each category or a claim that either member exclusively produced a shared feature. The Canvas template records the final contribution scores; the evaluation below supplies their qualitative justification.

2 Basis of the assessment

Shared 3D development: both members shaped the direction and early work. Rijan led the later Three.js implementation and integration; Sushank led the UI and responsive presentation. Both contributed to task and interface decisions. This recognises complementary work without assigning exclusive ownership of the whole feature or changing the recorded assessment allocation.

The assessment considers motivation and responsibility, time management, adaptability, creativity and originality, communication, general team skills and technical skills. Relevant evidence includes the developed learner and management routes, design and operation documents, retained client correspondence, shared identity material and individual reflection. Responsibilities are evaluated through their effect on the project, rather than by counting screens or assuming that the most technically difficult task deserves all the credit.

The two roles were complementary. A saved outcome needed an understandable explanation; a clear interface needed reliable data and permitted access. Shared work is recognised within the overall allocation without attributing the complete activity to both members separately. The assessment also considers shortcomings. A developed feature can represent substantial work while still requiring better verification or client clarification.

The categories overlap. For example, clarifying progress demonstrates technical reasoning, communication and teamwork, but those connections do not make it three independent contributions. Our overall judgement considers responsibility, the usefulness of the resulting work and how effectively the members joined their parts. It also separates an assigned responsibility from evidence that the complete outcome was achieved.

Attendance, punctuality, reminders and individual hours are not sufficiently recorded to assign precise judgements on those indicators. The 8 October worksheet date is retained; a separate date for the assessment discussion is not recorded. The improvement priorities are proposed future work and do not change the verified allocation.

3 Evaluation against the seven categories

A Motivation and responsibility

Rijan: His responsibility extended across coordination, authentication, database work, connected application behaviour and technical documentation. These areas support several journeys: a learner must reach the correct workspace, an outcome must be retained, and a trainer must receive only the permitted record. Taking responsibility across those dependencies is a substantial contribution. His self-reflection also recognises that broad requests could give Sushank too much work without a sufficiently clear expected result. Coordination therefore needed better task definition as well as continued implementation.

Sushank: His frontend and visual responsibilities produced the means through which learners and trainers use the system. Lesson layout, navigation, account forms, task instructions and responsive controls were substantive deliverables. His role also covered branding and presentation visuals, while the promotional website was shared work. This supports recognition of sustained responsibility for the user-facing product. Its quality still depends on checking that labels, actions and saving messages accurately reflect the underlying behaviour.

Assessment: Both members accepted significant areas of the project. Rijan's wider coordination and integration responsibility supports additional recognition, while Sushank's ownership of the interface makes his contribution essential to the connected outcome. The weakness was treating a technical part and its visible explanation as separately finished. Responsibility should include identifying an unresolved dependency and agreeing who will close it, alongside producing the assigned work.

B Time management

Rijan: Prioritising backend foundations and one focused Fire Safety journey gave later supervision and practice a usable starting point. The later plan kept curriculum and supervision in Weeks 8–9, integration and testing in Weeks 10–11, and handover in Week 12, with UI and 3D work overlapping. His reflection identifies the risk of modelling, cameras and animation consuming time without improving the learner's next decision. Smaller tasks with explicit completion conditions would have made that work easier to coordinate and review.

Sushank: Frontend development had to continue alongside changing task states, records and management permissions. His navigation, layout and control responsibilities therefore depended on timely technical explanations rather than a finished backend handed over at the end. Reviewing one screen with its example data and expected next action would have reduced ambiguity and made interface work easier to schedule.

Assessment: The focused initial route and overlapping later work show a sensible response to a two-person team's capacity. The continuation period ended with the client presentation on 9 October. Scope decisions are clearer evidence of time management than an unsupported claim of punctual completion. A shared checkpoint should distinguish implementation, verification and submission preparation, so unfinished integration is visible before another task depends on it.

C Adaptability

Rijan: The client's 7 September concern about progress required a change in meaning, not just a different percentage display. Rijan's calculations and records needed to distinguish reading, assessment, practice and certificate outcomes. His later responsibilities also extended from the learner foundation to trainer scope, account operations and guided-task recording. These connections show application of existing technical skills to changing requirements.

Sushank: The same feedback required clearer labels, instructions, record categories and saving states. His layout and interaction work translated technical distinctions into information a learner or trainer could use. The 21 September request for simpler controls on smaller screens also connects his responsive interface responsibilities to the client's working context.

Assessment: Both roles contributed to the response to constructive criticism. Adaptation remains incomplete where implementation and requirements differ: trainer account creation needs an explicit client decision, and the simplified spill and isolation tasks omit procedural choices. The progress response is stronger because it changes both record meaning and presentation. Other changes need that same comparison with the original concern, supported by independent learner interpretation and qualified procedure review.

D Creativity and originality

Rijan: Guided tasks connect a workplace scene, an accepted action, an explanation and a recorded outcome. His technical task and motion integration gave the continuing 3D work a learning purpose. This is a useful design contribution because an attractive model alone would not explain what the learner should do or what the trainer should understand afterwards.

Sushank: Visual hierarchy, typography, responsive composition and named controls made the application easier to interpret. His visual responsibilities helped connect the system, promotional material and presentation through a recognisable identity. The original peacock symbol and Primary Blue (#0056D2) remain part of that identity.

Assessment: The logo, typography and colour refinement were shared. Rijan's account describes dissatisfaction with the initial monogram and substantial joint revision. Both members therefore deserve recognition for the resulting identity. Creative contribution is strongest where a visual or technical choice helps explain the project's specific learning need. Retaining the alternatives and reason for the choice would make that judgement easier to assess; a recognisable identity or added scene alone does not measure learner understanding.

E Communication skills

Rijan: His coordination, technical explanation, design diagrams, reports and operation guidance connect implementation to client review and handover. Early client messages were signed by him. His self-assessment identifies a communication weakness within the team: a broad instruction could leave the recipient with too much work and insufficient clarity about the expected result. Giving a bounded example, dependency and review condition would make those handovers more effective.

Sushank: Later client messages were signed by him on behalf of both members. They asked focused questions about task relevance, trainer information, devices and final-review priorities, making his contribution visible beyond visual production. His interface wording and presentation visuals also communicated the project through different forms. Their effectiveness needs to be judged through what a reader or learner understands, alongside their appearance.

Assessment: The correspondence shows useful written questions and confirmation, while the documentation and visuals support explanation. Follow-through is the main weakness where a broad reply left a precise permission or procedure unresolved. The final presentation was delivered on 9 October, but preparation material does not establish each member's exact spoken performance. A stronger review would close a specific question with the client's actual decision, a named follow-up owner and the next review condition, leaving an unanswered point open.

F General team skills

Rijan: His account acknowledges that collaboration was difficult initially. Learning to separate responsibilities and give manageable tasks was an important improvement in leadership. Keeping extensive implementation responsibility himself also made it necessary to explain dependencies clearly so Sushank could review the consequence of a technical decision.

Sushank: His interface and visual responsibilities contributed a complementary perspective on how the application should be used and understood. Shared branding, interface decisions and promotional website work required both members' input. These joint activities show why effective teamwork involved reviewing the other member's contribution as well as completing an assigned part.

Assessment: A useful example is progress information: Rijan's stored calculation and Sushank's label needed to communicate the same achievement. Shared logo refinement also required both members to accept revision. These examples support recognition of complementary teamwork, while the initial task-handover difficulty shows its cost when expectations were unclear. Joint review should let each member challenge the other's result and resolve the disagreement through the complete user action, including failure and interruption.

G Technical skills

Rijan: His work connected authentication, permissions, database records, scoring, guided-task state and technical integration. The progress-storage correction discussed in his personal evaluation illustrates his strength in tracing a visible failure to record identity rather than only changing a completion indicator. These responsibilities have consequences across the application and support the larger technical share. The self-assessment also identifies a need to record expected behaviour, actual results and unresolved conditions more consistently.

Sushank: Frontend implementation required more than visual styling. Navigation, responsive forms, record tabs, task controls, loading and error states had to remain coherent across learner and management routes. A backend result becomes usable only when the interface identifies the correct person, explains the outcome and offers an appropriate next action. These responsibilities warrant substantial technical recognition.

Assessment: The developed routes demonstrate complementary technical contributions. Retry, account-cleanup, interrupted-save and task-history checks require shared verification. These future checks do not establish either member's performance on an earlier date. Rijan should lead record and permission corrections; Sushank should compare visible states and recovery actions with the actual result. Their joint completion condition is a matching, permitted learner-to-trainer outcome, including the interrupted route.

4 Overall self and peer evaluation

Rijan's strongest contribution was connecting the system's identity, data and outcomes while coordinating the wider project and explaining its operation. His self-reflection is appropriately critical of broad task handovers and giving implementation more attention than recording verification. The larger allocation recognises the breadth of his work; it does not excuse those weaknesses. His improvement is to define a manageable task, share the expected record and visible result, and retain a clear verification outcome.

Sushank's strongest contribution was making the developed behaviour accessible through frontend implementation, responsive layout, visual identity and communication. The retained work supports a substantial contribution to both the application and how the team presented it. Further improvement should focus on testing explanations and recovery with a complete user action, rather than judging a screen's clarity through appearance alone.

The 60%/40% allocation is supported by Rijan's wider combination of technical integration, coordination and documentation, alongside Sushank's substantial frontend, design and communication contribution.

Creativity, adaptability and teamwork include significant shared work. The percentages do not imply that Rijan contributed more in every category, and no unrecorded category scores or numerical weighting have been added.

5 Shared work and improvement priorities

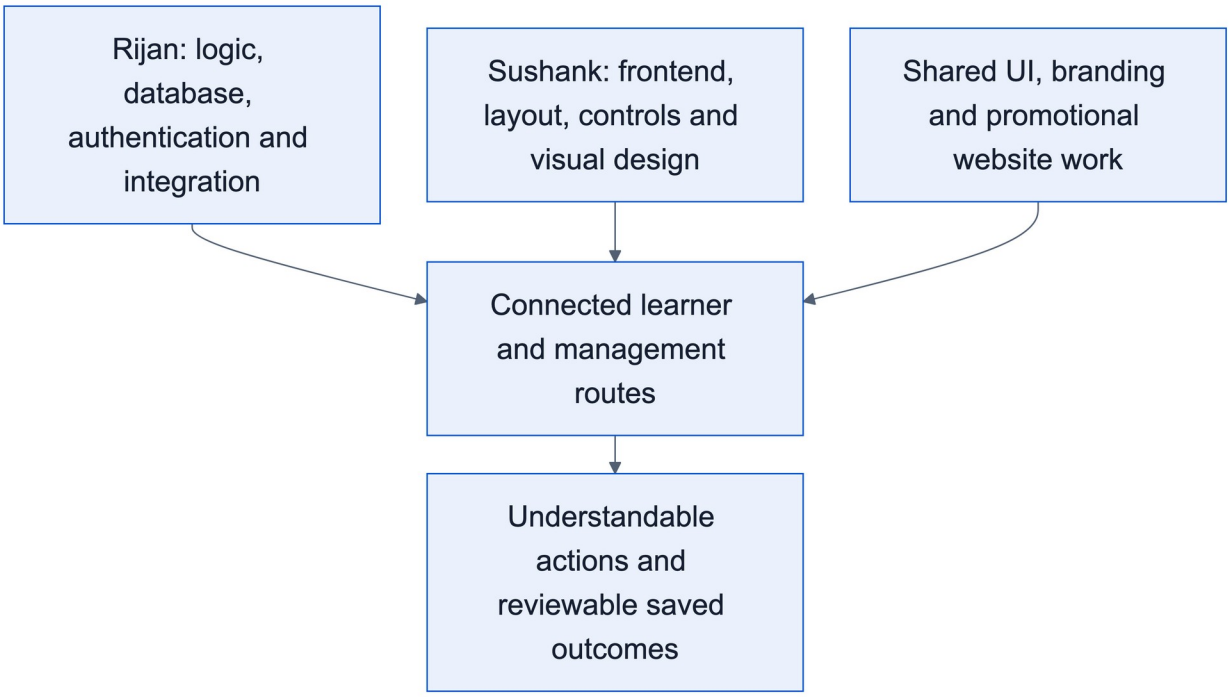

Figure 1 How the team's technical and interface responsibilities depend on each other.

Guided practice provides a concrete example of the relationship. Rijan's task logic and recording need Sushank's instruction, controls and status information. A completed scene must be distinguished from a confirmed saved record, and the authorised trainer must receive the matching outcome. Both members should review those relationships before describing the activity as dependable.

For a continuation, we would turn the seven categories into the working commitments below. Each pairs a manageable individual responsibility with an outcome both members can review. These are future improvements, rather than additional completed contributions or a change to the verified scores.

Table 2 Proposed working commitments across the seven categories

Assessment category	Rijan's next contribution	Sushank's next contribution	Shared completion condition
A Motivation and responsibility	Define the task owner, dependency and expected stored outcome	Confirm the instruction, action and status that the task requires	Both can explain the outcome and identify who owns each unresolved dependency
B Time management	Break integration into a bounded route and identify its prerequisite checks	Estimate the related screen/control work and flag blocked dependencies	A checkpoint records what is implemented, verified and still open; revised priorities are explicit

Assessment category	Rijan's next contribution	Sushank's next contribution	Shared completion condition
C Adaptability	Trace a client request to permissions, calculations or task rules	Show its effect on controls, explanation and record categories	The response is compared with the original concern; authority and qualified procedure decisions are recorded before acceptance
D Creativity and originality	Explain why a scene or interaction supports the learner's decision	Compare visual/control alternatives while retaining SARAS identity	One useful choice, its alternative and rationale are retained and reviewed for learner understanding
E Communication skills	State the technical decision and its consequences in a bounded question	Supply the corresponding example and record the actual response	The client decision, follow-up owner and review condition agree; unanswered questions remain open
F General team skills	Invite review of the technical result and explain its dependencies	Review the user action and invite challenge of its wording and layout	Both inspect instruction, response and record together and resolve differences before accepting the task
G Technical skills	Correct and verify identity, scoring, saving and partial-write behaviour	Match loading, failure, saved and retry messages to the actual result	Permitted and denied paths agree with stored state; interruption produces accurate status and supported recovery

Begin with the known save/recovery defects because they connect both members' responsibilities and affect an existing route. A practice task would need the required decision, explanation, saved outcome and correct trainer view before a new scene became the next priority. Review any failed condition together and retain the actual limitation instead of treating visual completion as the end of the task.

The allocation includes shared promotional work. Later poster and presentation submission revisions do not change the assessment recorded on 8 October. This assessment therefore recognises substantial contributions while committing future work to more complete and reviewable outcomes.

6 Assessment sheets supplied

The B5 folder contains one Canvas-template spreadsheet named for each member: Self and Peer Assessment — Rijan Kapur Poudel and Self and Peer Assessment — Sushank Jung Rawal. Both list Poudel before Rawal, as required by alphabetical surname order, identify Team 9 and SARAS Labs, retain the 8 October date, and record 60 and 40 with a total of 100. The entries are whole-number contribution percentages in the supplied score fields.

These two individual sheets are the scored assessment records. This evaluation explains the contribution judgement and its improvement priorities; it does not replace either student's sheet. The lecture guidance requires individual completion before the supervisor review. A separate supervisor signature is not recorded, and score verification does not establish one.
